

1. Difference between block level and inline elements

The block level elements refers to the elements that are stacked one below the other according to the width, height available across the page of the container

Example : <div> <h1> - <h6>

It starts on a new line

Takes up full width

Can contain other elements

Styling flexibility

2. Learn examples with <div>, <p>(block) and , <a> (inline)

HTML elements are categorized as either block-level (like <div> and <p>) or inline (like and <a>). Block elements always start on a new line and take up the full width available, while inline elements only take up as much width as necessary and flow within the surrounding content.

3. Headings <h1> - <h6>

<h1> through <h6> are HTML tags defining six levels of section headings, from most important (<h1>) to least important (<h6>), creating a semantic structure for content, guiding users and search engines, with browsers automatically styling them from largest to smallest. They establish hierarchy, like a book's chapters (H1 for main title, H2 for sections, H3 for subsections)

4. Create a sample page using block and inline elements
